## Group Problem Set \#3

1. Describe how you could experimentally determine the amount of memory allocated to a program.
2. Here is a traditional recursive solution to compute $x^{n}$
```
double power(double x, int n)
{
    If (n == 0)
            return 1;
    return n * power(x, n-1);
}
```

However, is it really necessary to make eight multiplications to compute $x^{8}$ ?
It can be observed that:

$$
\begin{aligned}
& x^{8}=\left(x^{4}\right) *\left(x^{4}\right) \\
& x^{4}=\left(x^{2}\right)^{*}\left(x^{2}\right) \\
& x^{2}=x^{*} x
\end{aligned}
$$

That is, only 3 multiplications are needed. Using this observation, improve the recursive algorithm for computing $x^{n}$. Hint: A separate case is needed for odd exponents.
